DISCS

# Collision

- After determining acceleration and computing for new positions and velocities, check for collision

```
// the code template below is wrong
```

```
// what should it be?
```

```
for( int i = 0; i < numObjects; i++ )
```

$$\{$$

```
// move object[i]
```

```
// collision check for object[i]
```

[illegible]

# Collision

- ▶ First, do a pairwise check for overlap
  - ▶ For shapes other than circles, you'll have to figure that out yourself (or wait for later lessons for convex polygons)
- ▶ Then, if there is overlap, check if the two objects are actually moving into each other
  - ▶ Both stationary or moving away from each other? No collision!

001010100101010001111001101010010101  
10001100100001111001101010010101  
11001010101010100001001100101010100  
100101001001001010101010101010101  
11100001111010110000000111101001

10010100100001010100100101001010  
1001010010101001010010101010101

# Collision

- ▶ Checking for overlap between circles is easy
  - ▶ How?
- ▶ But how do we know if two objects are moving into each other?

00101010010101010001111001101010010101  
10001100100001111001101010010101

1001010010001010100100101001010  
100101001010100101001010010101

DISCS

# Collision (After Overlap Check)

- ▶ First, determine a normal vector for the point of collision
  - ▶ Easy for circles – it's the vector we use to determine distance
  - ▶ Easy for edges – it's a vector perpendicular to the edge (facing away)
  - ▶ For other stuff – you'll have to look it up
- ▶ Note: The normal is normally normalized (but you can skip that step... for now)

# Collision (After Overlap Check)

- ▶ Next, determine relative velocity of one object to the other
  - ▶ Relative velocity of object A to object B  
 $= \text{velocity\_of\_A} - \text{velocity\_of\_B}$
  - ▶ **IMPORTANT:** ALL equations (including the one above) in this slide set assume collision normal is pointing from object B to object A

0010101001010100011110100001100  
10001100100001111001101010010101  
110010101010100001001100101010100  
1001010010010010101010101010101  
11100001111010110000000111101001  
001001010100101001001010010010110  
1001010010001010100100101001010  
100101001010100101001010010101

DISCS

# Collision (After Overlap Check)

- ▶ At this point, you have a collision normal vector and a relative velocity vector
  - ▶ What does it mean if they're pointing away from each other?
  - ▶ What does it mean if they're pointing in more or less the same direction?
  - ▶ And how do we determine where they're pointing (relative to each other) in code?

# Collision (After Overlap Check)

- ▶ If the relative velocity vector is pointing away from the collision vector (more than 90 degrees) then you have a collision
- ▶ Now we should determine what happens as a result of the collision
  - ▶ In other words, we need to use various collision response equations
  - ▶ Reminder: No need to normalize collision normal... for now

001010100101010001111001101010010101  
10001100100001111001101010010101  
11001010101010100001001100101010100  
100101001001001010101010101010101  
11100001111010110000000111101001  
001001010100101001001010010010110  
1001010010001010100100101001010  
100101001010100101001010010101

# Impulse

- ▶ Since we need to change object velocities instantaneously, we need to compute for impulse and apply it to the object velocities
  - ▶ Can't rely on applying forces normally because it'll take at least one timestep for the resulting change in accelerations to affect velocities

001010100101010001111001101010010101  
10001100100001111001101010010101  
110010101010100001001100101010100  
100101001001001010101010101010101  
11100001111010110000000111101001  
001001010100101001001010010010110  
10010100100001010100100101001010  
100101001010100101001010010101

# Impulse

- ▶ However, just like friction, the effect of impulse depends on the objects' masses
  - ▶ Lighter objects should be more easily moved
  - ▶ Incredibly heavy objects (i.e. infinite mass) shouldn't budge at all
  - ▶ We're actually changing momentum (which affects velocity)

001010100101010001111001101010010101  
110010101010100001001100101010100  
100101001001001010101010101010101

# Homework

- ▶ Modify your previous homework:
  - ▶ Your program should now require a command-line argument  $X$  that is an integer between 1 and 35, inclusive
  - ▶ In addition to the player-controlled circle, create  $X$  more circles
  - ▶ Positions should no longer be random to avoid initial overlapping

```
001010100101010001111001101010010101
10001100100001111001101010010101
